Single Deployment Unit (Recommended for simplicity)

This method bundles the built Angular application as static resources within the Spring Boot JAR file, which is then run on the server using its embedded Tomcat instance.

1. **Build the Angular Project for Production:** In your Angular project's root directory, run the production build command using the Angular CLI.

   bash

   ```
   ng build --prod
   ```

   This creates a `dist` folder containing optimized static files (HTML, CSS, JS).

2. **Integrate Angular Files into Spring Boot:** Copy the entire contents of the Angular `dist/<app-name>` folder into the `src/main/resources/static` directory of your Spring Boot project. (You may need to create the `static` folder if it doesn't exist).

3. **Configure Spring Boot for Routing (if using client-side routing):** To handle client-side routing correctly, ensure your Spring Boot application forwards unknown requests to the `index.html` file by adding a controller or configuration that handles this.

4. **Package the Spring Boot Application:** In the root directory of your Spring Boot project, build an executable JAR file using Maven.

   bash

   ```
   ./mvnw clean package
   ```

   This creates a single JAR file in the `target` folder.

5. **Deploy and Run on the Server:** Transfer the generated JAR file to your company server and run it using the `java -jar` command.

   bash

   ```
   java -jar your-app-name-0.0.1-SNAPSHOT.jar
   ```

   Your application should now be accessible at the server's IP address and port (default is 8080).
